Homework 3 - Action Potential, H-H model

Solution

Problem 1.

Choose the correct answer.

1. What effect does an intravenous injection of KCl have on behavior of neurons?
 - (a) Extracellular K^+ decreases and therefore the membrane potential gets closer to Na^+ equilibrium potential.
 - (b) The membrane potential becomes more negative and it becomes more difficult to generate action potentials.
 - (c) Extracellular K^+ increases and therefore the membrane potential gets closer to Na^+ equilibrium potential.
 - (d) None of the above.

Answer: c

2. Photoreceptors in the retina have special channels that are open to Na^+ in the dark. When light hits photoreceptors, these special channels close. What can you conclude from this?
- (a) Photoreceptors depolarize to light.
 - (b) Photoreceptors hyperpolarize to light.
 - (c) Photoreceptor voltage does not change in the presence of light.
 - (d) None of the above.

Answer: b

3. According to the figure 1, the slow depolarization apparent in phase 4 is primarily due to:
- (a) The Slow L-type Ca^{2+} Channel.
 - (b) A slow, inward Na^+ current (funny current).
 - (c) A slow, outward Na^+ current (funny current).
 - (d) None of the above.

Figure 1: An action potential.

Answer: b

4. Drug X, when applied to a nerve axon, results in both a gradual decrease in the amplitude of individual action potentials and a depolarization of the resting potential, both of which develop over a period of several hours. The drug is most likely:

- (a) Blocking the voltage-dependent Na^+ permeability. (This answer is INCORRECT)

Blocking the voltage-dependent sodium permeability would decrease the amplitude of the action potential, but it would probably do nothing to the resting potential. If it did anything to the resting potential, it would lead to a hyperpolarization, not a depolarization as is the case with drug X.

- (b) Blocking the voltage-dependent K^+ permeability. (This answer is INCORRECT)

The voltage-dependent potassium channels are generally not activated unless the membrane potential is fairly depolarized. Thus, blocking the voltage-dependent potassium permeability would have very little, if any, effect on the resting potential. Also, blocking the voltage-dependent potassium permeability would have a tendency to perhaps increase the amplitude (and duration) of the action potential rather than decreasing it.

- (c) Blocking the (Na^+ - K^+) pump. (This answer is CORRECT)

Blocking the sodium potassium pump leads to a gradual influx of sodium into the cell, and efflux of potassium out of the cell. These changes in concentration lead to a change in the equilibrium potential for potassium, as well as for sodium. As the equilibrium potential for potassium becomes more positive, the resting potential becomes more positive (i.e., more depolarized). Because of the sodium influx into the cell, the equilibrium potential for sodium is changed, namely, it is less positive. And because the peak amplitude of the action potential is dependent upon the value of the sodium equilibrium potential, the peak amplitude of the action potential would also decrease over time.

- (d) Blocking the process of Na^+ inactivation. (This answer is INCORRECT)

Blocking the process of sodium inactivation would affect primarily the repolarization phase of the action potential. There would be no change in the resting potential. The only consequence would be that the action potential would have a greater duration than normal.

- (e) Increasing the rate at which voltage-dependent changes in K^+ permeability occurs. (This answer is INCORRECT)

Increasing the rate in which voltage-dependent changes in potassium permeability occur would only affect the duration of the action potential. Perhaps if there was an increase in the rate, there might also be a slight decrease in the amplitude of the action potential, but there would be no change in the resting potential.

Answer: c

5. Reducing the concentration of extra-cellular Na^+ , reduces the amplitude of action potential.
- (a) True
 - (b) False

Answer: a

6. The rising phase of the action potential is controlled by the parameter:
- (a) m (The probability that a Na^+ activation gate is open.)
 - (b) h (The probability that a Na^+ inactivation gate is open.)
 - (c) n (The probability that a K^+ gate is open.)
 - (d) All of the above.

Answer: a

Problem 2.

In an action potential, how many Na^+ ions must move into the axon to cause a depolarization of 100 mV?

Suppose the length of a cylindrical axon is 100 μm , and it has a radius of 4 μm . Assume the thickness of the membrane is 10 nm and the dielectric constant is 7.

(Equations and constants are provided. Please be sure that you show units.)

$$Q = C \cdot \Delta E, \quad (\text{coulombs}) = (\text{coulombs/volt}) (\text{volt})$$

$$C = \frac{\kappa \cdot \epsilon_0 \cdot A}{d}$$

$$\epsilon_0 = 8.85 \cdot 10^{-12} \text{ (F/m)}$$

$$\text{Elementary charge} = 1.60 \cdot 10^{-19} \text{ coulombs}$$

$$C = \frac{k \epsilon_0 A}{d} = \frac{k \epsilon_0 (r_R r_L)}{d}$$

$$= \frac{7.885 \times 10^{-12} \cdot (2r)(4 \times 10^{-6} \text{ m})(10^{-4})}{10 \times 10^{-9}}$$

$$= 1.6 \times 10^{-11} \text{ (F)}$$

$$\Delta Q = C \cdot \Delta V$$

$$= 1.6 \times 10^{-11} \times 100 \times 10^{-3} = 1.6 \times 10^{-12} \text{ (C)}$$

$$\frac{\Delta Q}{e} = \frac{1.6 \times 10^{-12}}{1.6 \times 10^{-19}} = 10^7$$

$$= 10 \text{ million } \text{Na}^+ \text{ ions}$$

cell membrane : dielectric

Problem 3. The effects of toxins on different channels.

Researchers at Duke University discovered in the 1960s that a toxin (Tetrodotoxin (TTX)) isolated from the ovaries of the puffer fish could selectively block the sodium channel. TTX blocks all sodium-dependent action potentials and therefore is usually fatal if ingested.

- (a) Another important compound that can affect certain ion channels is Tetraethylammonium (TEA). What does it do? (If you don't know, search the web)
- (b) According to the figure 2 from a voltage-clamp experiment, we can see a time-dependent inward ionic current followed by a time-dependent outward ionic current. A hypothesis proposes that there are two sets of voltage-gated channels: Voltage-gated sodium and voltage-gated potassium channels. First, design an experiment to isolate Na^+ and K^+ currents and then draw Na^+ and K^+ currents separately.

Figure 2: A voltage-clamp experiment demonstrates the sequential activation of voltage-gated sodium and potassium channels.

Answers:

a) It blocks potassium channels.

b) Simple answer is to add in TTX (tetrodotoxin) to isolate K currents (blocks Na channels), and TEA (Tetraethylammonium) to isolate Na currents (blocks K channels). Or change the ion bathing solutions in voltage-clamp. To isolate K currents, use H^+ instead of Na^+ .

Problem 4.

In a physiological experiment, the following data is collected. The membrane thickness is 10 nm and We know that the rest potential is -88.5 mV. ($kT/q \simeq 26.7\text{mv}$)

$[\text{Na}^+]_i = 12 \text{ mMol/lit}$	$[\text{K}^+]_i = 155 \text{ mMol/lit}$	$[\text{Cl}^-]_i = 4 \text{ mMol/lit}$
$[\text{Na}^+]_o = 145 \text{ mMol/lit}$	$[\text{K}^+]_o = 5 \text{ mMol/lit}$	$[\text{Cl}^-]_o = 110 \text{ mMol/lit}$

- Calculate V_{Na} and V_K .
- Calculate α and β for each parameter of Hodgkin-Huxley model. i.e. n , m , h .
Using α and β parameters, find an equation for $m(t)$, $n(t)$ and $h(t)$. What are their steady-state values?
- Calculate g_{Na} and g_K at rest. ($\bar{g}_K = 24.31 \text{ mmho/cm}^2$, $\bar{g}_{Na} = 42.9 \text{ mmho/cm}^2$)
- Assume $g_L = 0.3 \text{ mmho/cm}^2$. Calculate V_L so that it is compatible with the values you calculated in previous parts.
- Calculate I_{ext} ($\mu \text{ A/cm}^2$) so that V_{rest} becomes -80 mV.

میخواهیم در حالت استراحت پارامترها را حساب کنیم، لذا ولتاژ را در فرمول صفر میگذاریم:

$$V_{Na} = \frac{kT}{q} \ln \frac{C_{out}}{C_{in}} = \frac{26.7}{1} \ln \frac{145}{12} = 66.53 \text{ mV}$$

$$V_K = \frac{kT}{q} \ln \frac{C_{out}}{C_{in}} = \frac{26.7}{1} \ln \frac{5}{155} = -91.68 \text{ mV}$$

$$\alpha_n(V) = \frac{0.1 - 0.01V}{e^{1-0.1V} - 1} = 0.05$$

$$\beta_n(V) = 0.125 e^{-\frac{V}{80}} = 0.12$$

$$\tau_n = \frac{1}{\alpha_n + \beta_n} = \frac{1}{0.05 + 0.12} = 5.46 \text{ ms}$$

$$n(t) = n_{\infty} - n_{\infty} e^{-\frac{t}{\tau_n}}$$

$$\alpha_m(V) = \frac{2.5 - 0.1V}{e^{2.5-0.1V} - 1} = 0.22$$

$$\beta_m(V) = 4 e^{-\frac{V}{18}} = 4.01$$

$$\tau_m = \frac{1}{\alpha_m + \beta_m} = \frac{1}{0.22 + 4.01} = 0.23 \text{ ms}$$

$$m(t) = m_{\infty} - m_{\infty} e^{-\frac{t}{\tau_m}}$$

$$\alpha_h(V) = 0.07 e^{-\frac{V}{20}} = 0.07$$

$$\beta_h(V) = \frac{1}{e^{3-0.1V}} = 0.04$$

$$\tau_h = \frac{1}{\alpha_h + \beta_h} = \frac{1}{0.07 + 0.04} = 8.52 \text{ ms}$$

$$h(t) = h_{\infty} - h_{\infty} e^{-\frac{t}{\tau_h}}$$

$n(t) = \dots$
 $\tau_n \frac{dn}{dt} = -n + n_{\infty} \xrightarrow{\text{Laplas}} (\tau_n s + 1)N = \frac{n_{\infty}}{s}$
 $N = \frac{n_{\infty}}{s(\tau_n s + 1)} = \frac{n_{\infty}}{s} + \frac{-n_{\infty}}{\tau_n s + 1}$
 $\xrightarrow{\text{Laplas inverse}} n(t) = \left[n_{\infty} - n_{\infty} e^{-\frac{t}{\tau_n}} \right] u(t)$

$V = V_m - V_{rest} = H-H_{rest}$ (طبق تعریف)

$$g_{Na} = \bar{g}_{Na} m^3 h = 42.9 \times 0.05^3 \times 0.59 = 3.8 \times 10^{-3} \frac{mA}{cm^2}$$

$$g_K = \bar{g}_K n^4 = 29.31 \times 0.31^4 = 0.2476 \frac{mA}{cm^2}$$

(با توجه به مقدار زیاد g_{Na} و g_K نسبت به g_L و I_{ext} می‌توانیم فرض کنیم که g_L و I_{ext} در معادله $C \frac{dv}{dt}$ قابل چشم‌اندازی نیستند)

$$C \frac{dv}{dt} = g_{Na} (V_{Na} - V) + g_K (V_K - V) + g_L (V_L - V) + I_{ext} \quad g_L = 0.3 \frac{mA}{cm^2}$$

$$\xrightarrow[\frac{dv}{dt} = 0, I_{ext} = 0]{rest} 0 = 3.8 \times 10^{-3} (66.53^m + 88.48^m) + 0.2476 (-91.68^m + 88.48^m) + 0.3 (V_L + 88.48^m)$$

$$\Rightarrow V_L = -87.80^mV$$

$$C \frac{dv}{dt} = g_{Na} (V_{Na} - V) + g_K (V_K - V) + g_L (V_L - V) + I_{ext}$$

$$\xrightarrow[\frac{dv}{dt} = 0]{steady state}$$

در حالت پایدار، $\frac{dv}{dt} = 0$ و $I_{ext} = 0$ می‌باشد.
در این حالت می‌توانیم معادله را به صورت زیر بنویسیم:

در این حالت چون می‌خواهیم مجدد در حالت استراحت حساب کنیم، ولتاژ را در فرمول‌های آلفا و بتا صفر می‌گذاریم.

$$g_{Na} = 3.8 \times 10^{-3}$$

$$g_K = 0.2476$$

$$I_{ext} = -[g_{Na}(66.53+80) + g_K(-91.68+80) + 0.3(-87.80+80)] = 4.67 \text{ uA/cm}^2$$

Problem 5.

Plot the following graphs in MATLAB based on equations in the lecture slides.

Figure 3: The voltage-dependent functions of the Hodgkin-Huxley model.

Answer: The m-file is attached.

Problem 6.

In this exercise, we will use a MATLAB script (HH.m) that implements a simulation a single-neuron action potential based on Hodgkin-Huxley model using Euler's method under a current clamp experiment.

Current clamp means that we control the external current applied and measure the membrane potential in response to our manipulation. Note that this is different from voltage clamp in which we control the membrane potential and measure the ionic current.

In particular, this script is set to apply a depolarizing external current of $10 \mu\text{A}/\text{cm}^2$ for 10 milliseconds.

- (a) Complete the provided MATLAB code (file HH.m) and plot output voltage for a depolarizing external current of $10 \mu\text{A}/\text{cm}^2$ for 10 milliseconds. Your output should be similar to figure 4.

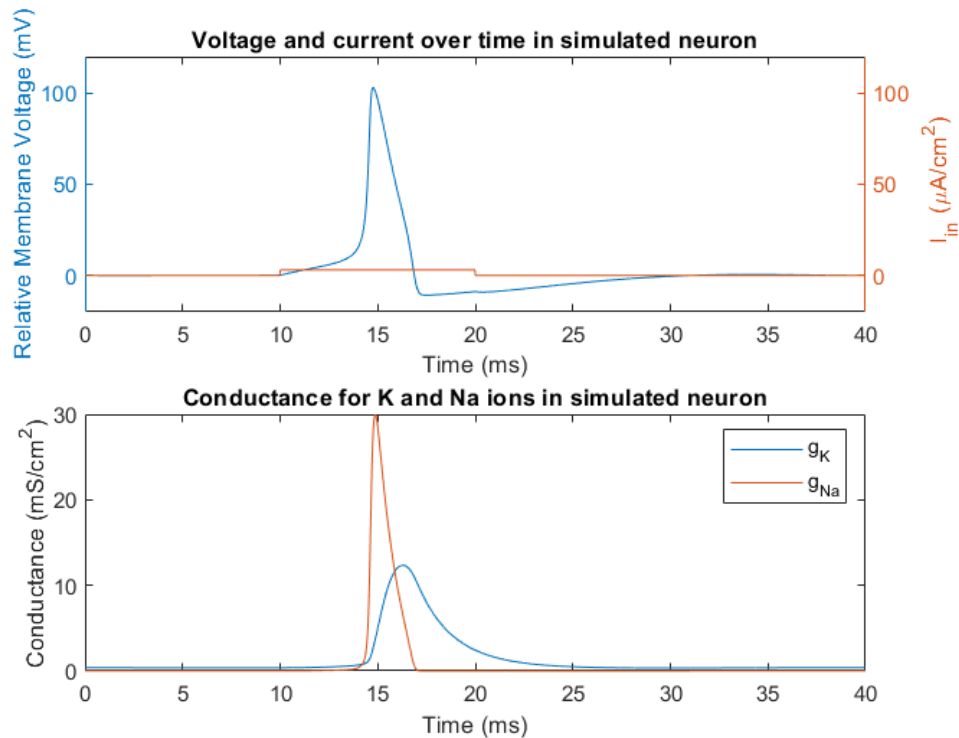

Figure 4: Membrane voltage (relative to resting potential) and voltage-dependent conductances for the Hodgkin-Huxley model.

- (b) Find minimum amplitude of external current with duration of 10 milliseconds causes an action potential.
- (c) Find minimum duration of external current with amplitude of $3 \mu\text{A}/\text{cm}^2$ causes an action potential.

- (d) Does the threshold for firing an action potential depend on the shape of the current pulse injected into the cell or does it only depend on the total charge injected? Explain your answer.
- (e) Make a copy of HH.m and call it HHpaired.m. Modify this file to apply two current pulses, each of amplitude $3 \mu\text{A}/\text{cm}^2$ and a duration of 10 milliseconds. The pulses should have an inter-pulse interval of 10 milliseconds which means they are separated by 10 milliseconds measured from the end of the first pulse to the start of the second pulse. Look at the plots and comment on what you see.
- (f) Modify the code so that the inter-pulse interval is now 2 milliseconds but keeping the amplitude at $3 \mu\text{A}/\text{cm}^2$. Look at the output plots, what has changed from the previous case? Find minimum inter-pulse interval that causes an action potential.
- (g) **(Extra question)** Plot HH variables (m , n , h) and the membrane currents (I_K , I_{Na} , I_{Leak}) using HH.m on the same figure vs time.

Answer:

- a) The m-file is attached.
- b) $2.3 \mu\text{A}/\text{cm}^2$
- c) 2.9 ms
- d) We can conclude from b and c or applying another current function that the threshold for firing an action potential only depends on the total charge injected.
- e) The m-file is attached.
- f) 4.9 ms
- g)
